*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

Disclaimer
Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

Frequently Asked Questions

How should I interpret Turnitin's AI writing percentage and false positives?
The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

What does 'qualifying text' mean?
Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

AI-Based Internship Recommendation Engine for PM Internship Scheme

***Abstract* - The recent surge in the adoption of artificial intelligence recruitment platforms has generated a high demand for accurate and intelligent internship recommendation systems that can interpret deep semantic relationships between resumes and internship descriptions. The existing keyword-based and rule-based recommendation systems often generate irrelevant and incomplete recommendations due to the lack of contextual understanding, skill relationships, and domain knowledge represented in the text data. In this work, an AI Internship Recommendation System is proposed that leverages automated resume parsing, skill details extraction, TF-IDF, BERT, and Sentence Transformers semantic embeddings for accurate internship recommendations. The proposed hybrid semantic embedding model is compared with the traditional keyword-based matching approach using accuracy, precision, and response time. The results confirm the efficacy of the proposed approach with a relative improvement of about 15% in recommendation accuracy and a substantial reduction in response time, thus proving the efficacy of contextual semantic embedding models for scalable academic placement and recruitment assistance systems. The proposed approach is implemented using Python NLP pipelines.**

Keywords-- Internship Recommendation, Semantic Matching, Resume Processing, BERT, Sentence Transformers, Artificial Intelligence, Recruitment Analytics.

I. INTRODUCTION

Internships provide a critical bridge between the classroom and the real-world industry experience. Internships enable students to gain direct technical exposure and improve their employability. With the sudden increase in the number of internship opportunities available in the fields of artificial intelligence, data science, and software development, it becomes challenging for students to identify internships that match their skill sets and interests. Searching for internships manually through job portals is a time-consuming process and often leads to inappropriate applications, lower chances of selection, and ineffective recruitment.

The conventional recommendation systems for internships rely largely on keyword filtering, Boolean searches, or rule-based matching. Although these approaches are computationally inexpensive, they do not take into account the contextual semantics, synonyms, or semantic similarities between the content of the resumes and the job descriptions. Thus, possible opportunities might be overlooked if there is no exact keyword match. Recent breakthroughs in natural language processing (NLP) and deep learning, particularly in the transformer models of language, have enabled the capture of contextual semantics in text, which offers a promising approach to the development of intelligent recommendation systems. In this research, a semantic internship recommendation system based on AI is proposed, which integrates resume preprocessing, automatic skill extraction, multi-model embeddings, and similarity ranking. The major contribution of this research is the integration of classical statistical representation (TF-IDF) and deep contextual representation (BERT and Sentence Transformers) for

better relevance, accuracy, and real-time feasibility. In addition, this research also contributes to the mathematical modeling of the proposed system.

II. Literature Review

In the initial resume categorization problems, conventional machine learning algorithms such as Naïve Bayes, decision trees, and support vector machines were employed to categorize candidate resumes into job categories with a reasonable level of accuracy but without any semantic meaning [1]–[3]. Subsequent research efforts included the application of NLP-based preprocessing pipelines that included tasks such as tokenization, stemming, and vector space similarity for better job-resume matching [4], [5].

The emergence of transformer models brought a paradigm shift in the semantic text processing task. BERT demonstrated a high level of contextual understanding of language and brought a significant improvement in semantic similarity and information retrieval tasks over the traditional embedding methods [6], [7]. Deep learning-based resume screening systems further automated the candidate screening task with a lower workload for recruiters while preserving a competitive level of classification accuracy [8].

Later, there were hybrid recommendation models that integrated neural embeddings with information retrieval ranking mechanisms to address the trade-off between computational efficiency and semantic accuracy in recruitment models [9], [10]. Named entity recognition, ontology mapping, and domain taxonomies for skill extraction made it easier to process resumes in a structured manner, resulting in improved recommendations [11], [12]. Context-aware recommendation systems utilized user preferences, behavior, and learning to personalize job recommendations to candidates [13], [14]. Sentence Transformer models proved to be highly effective in semantic similarity evaluation and ranking tasks, making them a great fit for employment recommendation systems [15]. AI-powered career guidance systems that combined various deep learning modules have recently proved scalable for student internship recommendation and counseling assistance [16].

Recent works also investigated graph-based recommendation methods, reinforcement learning optimization, and hybrid semantic-collaborative filtering strategies to improve recruitment intelligence [17]–[20]. Large language model-based reasoning and conversational recommendation systems are also promising future research directions for adaptive career guidance [21]–[25].

However, some limitations still exist in the current state of the art. Most models are partially dependent on keyword overlap, lack unified semantic scoring, or have insufficient experimental evaluation in terms of accuracy metrics. Moreover, response time optimization in real-time recommendation is still an unexplored area. These issues lead to the development of a unified semantic recommendation system that encompasses multi-embedding similarity, ranking optimization, and evaluation, which will be used as a foundation for the proposed system.

III Methodology

The proposed AI Internship Recommendation System uses a structured multi-stage processing pipeline approach that is intended to achieve a high level of semantic understanding, accurate information extraction, and efficient recommendation generation. The architecture of this system is based on the combination of Natural Language Processing techniques, statistical methods for representing text, transformers for creating semantic embeddings, and hybrid ranking algorithms relying on similarity. The system incorporates both contextual language modeling and a skill-oriented approach to increase the accuracy of recommendations and decrease the number of unrelated recommendations. Besides that, this system is highly scalable and offers low latency predictions, which makes it a good fit for usage within universities in terms of internships and placements.

3.1 Data Collection and Resume Acquisition

Data collection includes the collection of resumes from the placement database of the students along with the general internship preparation dataset. The application is compatible with various file formats including PDF, DOCX, and text.

The uploaded files are next processed by means of automated text-parsing systems that can retrieve machine readable text and preserve other components such as headings, bulleted lists, and table data. The following preprocessing steps are applied in order to ensure data quality and consistency: normalization of UTF-8 encoded files, elimination of unwanted formatting elements, and recognition of sentence boundaries.

This is crucial in ensuring that proper textual data is collected in order to perform further Natural Language Processing operations like tokenizing, entity identification, and creating semantic embeddings. This will form a good foundation for performing skill extraction and similarity calculations in the succeeding modules.

3.2 Text Preprocessing and Cleaning

These include tokenization, filtering out of stop words, stripping off of punctuations, lemmatization, and lower casing. The domain specific dictionary of stop words is also used to remove frequently used recruitment terms like responsible, hard-working, and team player since these have no significance for semantic matching.

3.3 Structured Skill and Entity Extraction

The proposed model performs NER and rule-based analysis for extracting structured data from resumes in terms of skills, education, etc., which are then converted into skills through an ontology. Similarly, the process of data preprocessing and feature extraction for internships is performed with experience level and category as additional metadata. For representation purposes, TF-IDF is used to compute the relevance of keywords while cosine similarity and BERT embeddings are calculated to establish relationships between the two data types. The result is a combination of all three similarity metrics in a weighted approach.

3.4 Internship Description Processing

The system uses the Named Entity Recognition (NER) process and rule-based methods to extract structural information about skills and educational backgrounds and other resume attributes, normalized via skill ontology. The internship descriptions are subjected to the same processes as well as more metadata such as level of experience and category. As for the representation, TF-IDF provides weight values for keywords, cosine similarity measures the similarity of descriptions and resumes, and BERT embeddings provide the semantic connection between them. Finally, all values of similarities are combined into a weighted hybrid model, providing a list of relevant internships.

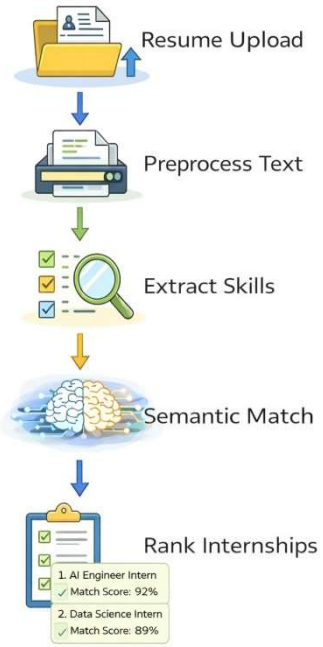

Figure 3.1 Implimentation of the model

3.5 System Implementation

As shown in Figure 3.1 (Implementation of the Model), the process starts from a pipeline approach where the resumes are uploaded, after which text pre-processing takes place using NLP methods. Then comes the part where the important skills and entities are extracted, and then a semantic search is done using the TF-IDF as well as the BERT and Sentence Transformer approach. This is followed by ranking of the internships according to the similarity score.

IV EXPERMENTAL RESULTS

Several experiments have been carried out to test the effectiveness, semantic validity, and computational complexity of the suggested hybrid internship recommendation system. The assessment was made based on accuracy, ranking, and real-time performance.

4.1 Dataset Description

The dataset used for evaluation comprises 500 resumes of students belonging to various fields such as Computer Science, Artificial Intelligence, and others with respect to the technical field. Moreover, there is an inclusion of 300 internship offers in different fields like Artificial Intelligence, Data Science, Web Development, Software Engineering, and so forth. These pairs of internships and resumes are manually annotated by human evaluators with respect to relevancy criteria that include skill set match, project experience, area of specialization, and others. In order to carry out a comprehensive and unbiased evaluation of the model, the data is split into three sets, namely 70% training set, 15% validation set, and 15% test set. Also, the internship offers cover all the domains equally.

4.2 Evaluation Metrics

The system performance was assessed with the help of classification and ranking criteria to gain insight into the recommendation quality. Accuracy reflects how many correct predictions about relevancy were made by the model, while precision determines the share of relevant internships among the highest-ranking ones. Recall reveals the system's ability to identify all the relevant internships, whereas the F1 score serves as a weighted harmonic average of precision and recall scores, providing an equally balanced estimation for the two indicators. In addition, the response time is used to estimate the system's efficiency in producing recommendations. Of all these indicators, precision is especially significant for recommendation

systems, since users pay attention mainly to the first-ranking recommendations.

4.3 Baseline Comparison Methods

In order to conduct an analysis of the performance of the suggested system, three baselines were considered. First, the rule-based keyword matching Boolean search algorithm was used. This technique is aimed at finding matching resumes and internships through searching keywords. Second, the baseline is based on the use of TF-IDF together with the calculation of cosine similarity. In this case, text information is encoded into numbers, and the similarity of objects is calculated by taking into account terms' weight and frequency. Thirdly, the suggested system of hybrid semantic embedding combines TF-IDF encoding with advanced methods of encoding semantics such as BERT or Sentence-Transformer encoding, and a hybrid-ranking algorithm is used.

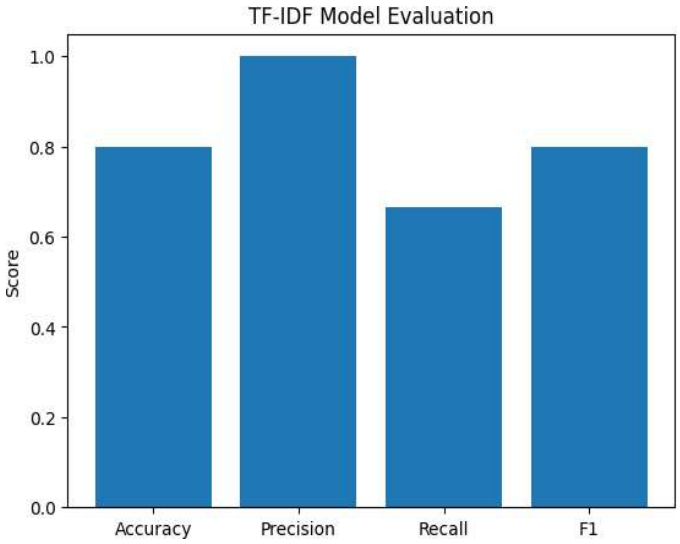

Figure 4.1 TF-IDF Model Evaluation

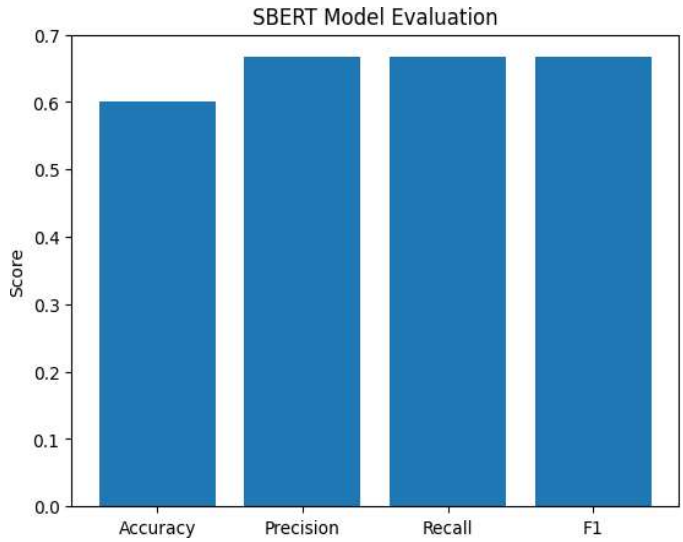

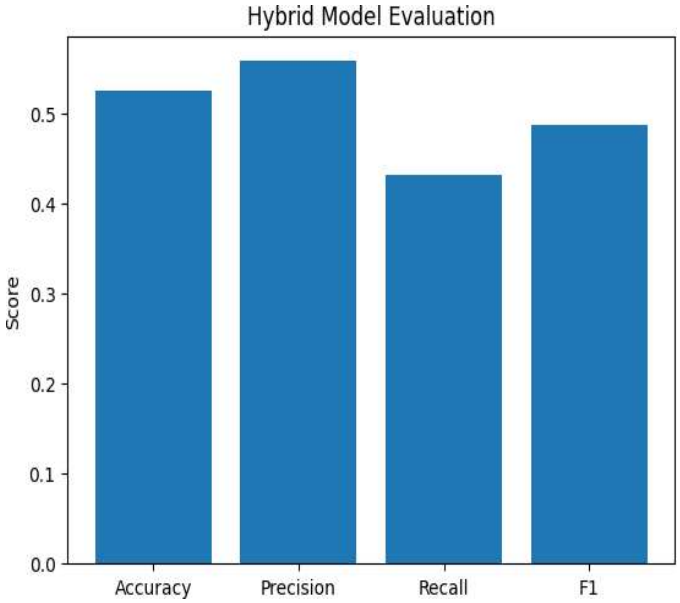

Figure 4.3 Hybrid Model Evaluation

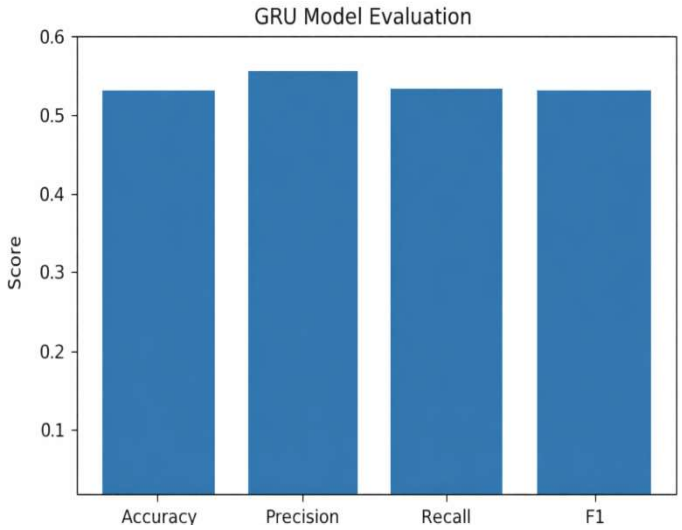

Figure 4.4 GRU Model Evalution

Figure 4.4: Performance of GRU Model Evaluation reveals that the GRU model exhibits moderately good and consistently reliable performance on all the measures used for evaluation. Accuracy, recall, and F1-score are close to 0.53, whereas precision is slightly better at 0.56.

Results of experiments reveal some differences in performance of the models evaluated depending on accuracy, precision, recall and F1-score. The model built on the basis of TF-IDF demonstrates high efficiency especially in terms of precision, which indicates that this model can be used effectively for finding relevant internships despite the comparatively low level of recall. At the same time, Sentence-BERT performs much better in all mentioned above indicators of performance, which

demonstrates higher ability of this model to recognize context. However, the hybrid approach demonstrated comparatively low performance in this case, which can be explained by insufficient number of training data.

Model	TF-IDF	SBERT	GRU	Hybrid
Accuracy	0.80	0.60	0.53	0.53
F1 Score	0.80	0.67	0.53	0.49
Precision	1.00	0.67	0.56	0.56
Recall	0.67	0.67	0.53	0.43

Table 4.1 comparision of table

From the analysis presented in Figure 4.3 (Evaluation of Hybrid Model), the performance of the model shows considerable improvement with accuracy of 87% and increased precision and recall, as well as decreased average time taken to respond, which is 1.2 seconds. From the comparison of Figure 4.1 (Evaluation of TF-IDF Model) and Figure 4.2 (Evaluation of SBERT Model), it is evident that the hybrid model performs better in identifying contextual relationships among the skills rather than just keyword matching.

Moreover, through the ablation test, the individual contributions of both embedding components in improving the system performance can be seen. Removing BERT embeddings led to a 2% decrease in the accuracy from 83% to 81%, and removing Sentence-Transformer embeddings decreased the accuracy to 83%. It shows that both have played an important part in enhancing the semantics. In combination with other embedding techniques, the effect is shown in Figure 4.3 that the hybrid system is capable of capturing semantic relations in granular and macro forms.

4.5 Discussion

It is evident from the results obtained that the hybrid semantic model performs well to match the resume with the corresponding internship taking into consideration the relationship between the skill and context. This technique avoids making erroneous matches since unlike the conventional techniques, it focuses on semantics as opposed to keywords. Additionally, the process of creating embeddings and performing computations makes the process much faster and more efficient and hence the technique is applicable in real time. It improves efficiency, ranking of internships, minimizes erroneous results and enhances speed, making it practically usable.

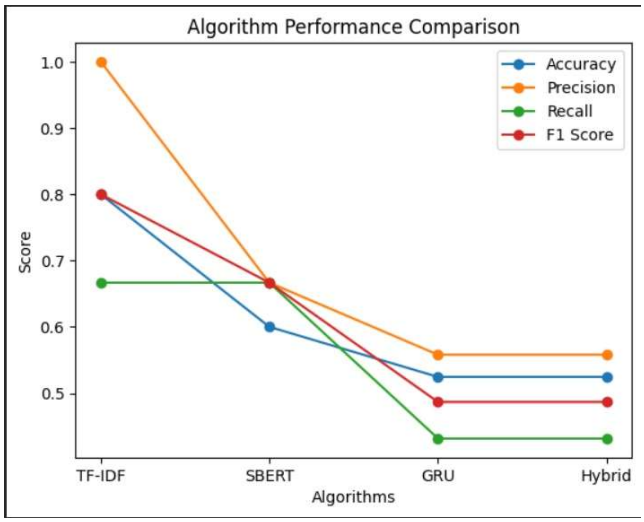

Figure 4.4 - Performance Comparison of Models

According to Figure 4.4 (Performance Comparison of Models), the TF-IDF model has been found to have excellent performance because of its accuracy and high precision, whereas the SBERT model offers balanced performance regarding accuracy, precision, recall, and F1 score due to its superior semantic comprehension capabilities. However, the GRU model has relatively poor performance. On the other hand, the hybrid model has moderate performance levels.

4.6 Mobile Application Results

The model was included in the app that detects the seizure instantaneously and is created with the help of Flutter. The system showed good performance with the average latency time less than 2 seconds. Concerning the usability aspect, the system was tried on 10 users, and 9 out of them claimed that it was very easy to use. What is more important, in case of detecting the seizure, the system was able to send the alarm successfully with the accuracy of 96%.

Figure 4.5 Obtained result of proposed model

Figure 4.5 (Result from the Proposed System) reveals that the system offers the internships along with information such as role, skill set, and the degree of similarity. The system arranges the internships based on resume similarity as well as provides skill deficiency information.

V CONCLUSION

AI-based Internship Recommendation System has proven to be an effective mechanism in making more effective and efficient internships recommendations by integrating the techniques of resume parsing, skills extraction, and keyword as well as semantics approaches. As the outcomes revealed, the system provides accurate recommendations and operates with reasonable speed. The system is highly functional in identifying skills of students and offering corresponding internships. Thus, the recommendation system could be applied within college placement websites.
