Paper Title

AI-Based Internship Recommendation Engine for PM Internship Scheme

Abstract

The recent surge in the adoption of artificial intelligence recruitment platforms has generated a high demand for accurate and intelligent internship recommendation systems that can interpret deep semantic relationships between resumes and internship descriptions. The existing keyword-based and rule-based recommendation systems often generate irrelevant and incomplete recommendations due to the lack of contextual understanding, skill relationships, and domain knowledge represented in the text data. In this work, an AI Internship Recommendation System is proposed that leverages automated resume parsing, skill details extraction, TF-IDF, BERT, and Sentence Transformers semantic embeddings for accurate internship recommendations. The proposed hybrid semantic embedding model is compared with the traditional keyword-based matching approach using accuracy, precision, and response time. The results confirm the efficacy of the proposed approach with a relative improvement of about 15% in recommendation accuracy and a substantial reduction in response time, thus proving the efficacy of contextual semantic embedding models for scalable academic placement and recruitment assistance systems. The proposed approach is implemented using Python NLP pipelines.
